

## REAGENČNÍ PROUŽKY DIRUI

### PRINCIPY REAGENČNÍCH PROUŽKŮ FY DIRUI (URISTIK A10)

Chemické semikvantitativní vyšetření moče diagnostickými proužky Uristik A10 (fy. Dirui). Jako měřící metody se využívá analytické metody imobilizované na pevném nosiči k semikvantitativnímu způsobu stanovení (reflexní fotometrie). Činidla jsou v suchém stavu imobilizována na reakčních ploškách a po styku proužku s močí reagují za vzniku barevné kolorimetrické reakce, která se odečítá v předepsaném čase reflexní fotometrií na močovém analyzátoru.

**I. Glukóza:** Glu se oxiduje glukosooxidasou (GOD), vznikající peroxid vodíku je rozložen katalásou a uvolněný kyslík oxiduje bezbarvý chromogen na modrozelený (event. hnědočervený) komplex. Test je specifický pro stanovení Glu. Barevná reakce je však reakcí na peroxidy, takže látky s vysokým oxidoreduktivním potenciálem ji mohou ovlivnit.

**Falešně negativní:** dává přítomnost kys. askorbové nad 0,2 g/l, dále vyšší koncentrace ketolátek (nad 3+). Reaktivita testu glu klesá se stoupající specifickou hmotností.

**U pozitivního nálezu glukózy postupujte takto:** (prověřeno měřením na přístroji Olympus AU 640)  
 trace (stopa) = 5,5 mmol/l  
 1+ = 14mmol/l  
 2+ = 28mmol/l  
 3+ - stanovit kvantitu (Olympus).

**II. Bilirubin:** Stabilizovaná diazoniová sůl v kyselém prostředí dává s bilirubinem růžově zbarvené azobarvivo.

**Falešně negativní:** reakci zeslabuje přítomnost kys. askorbové.

**Falešná pozitivita:** metabolity některých léčiv, které zabarvují moč.

**III. Ketony:** Test reaguje pouze s kyselinou acetooctovou. Nereaguje s acetonem a kyselinou beta-hydroxymáselnou. Acetoctová kyselina tvoří s nitroprusidem sodným v alkalickém prostředí za přítomnosti síranu amonného růžové až fialové zbarvení.

**Falešná pozitivita:** vysoká specifická hmotnost moči nebo nízké pH moči můžou vyvolat reakci podobnou stopovým množstvím ketonů. Také vzorky abnormálně pigmentované nebo vzorky s abnormálně vysokou koncentrací metabolitů levodopy.

**IV. Specifická hmotnosť:** Ploška obsahuje – bromthymolovou modř, polymer: methylvinylether sodné soli maleové kyseliny.

Tento test umožňuje stanovení spec. hmotnosti moči v rozsahu 1000 – 1030 kg/m<sup>3</sup>.

**V. Krev:** Hemoglobin působí jako pseudoperoxidasa a rozkládá organický peroxid (disopropylbenzen dyhydroperoxid) za vzniku kyslíku, který oxiduje přítomný chromogen (tetramethylbenzidin) na modrý produkt. Test je vysoce citlivý na hemoglobin a myoglobin. Citlivost testu může být snížena ve vzorcích moče s vysokou spec. hmotností.

**Falešná pozitivita:** mikrobiální peroxidasa produkovaná při infekcích močového traktu může vyvolat chybnou pozitivní reakci.

**VI. pH:** Směs indikátorových barviv (methylčerveň, bromthymolová modř) mění barvu od oranžové přes zelenou do modré v intervalu od pH 5 do pH 9.

**Příčiny chybných výsledků:** vzorek moči delší dobu po vymočení (2 hodiny a déle) podléhá amoniakálnímu kvašení a pH stoupá nad 7.

**Falešná pozitivita:** vysoká koncentrace kyseliny askorbové (vitamínu C) ve vzorce

**VII. Bílkoviny:** Test spočívá v posunu změny barevného přechodu indikátorového barviva (tetrabromfenolové modř) v přítomnosti bílkovin do alkaličtější oblasti (proteinová chyba pH-indikátoru!). Reagenční ploška je více citlivá k albuminu než ke globulinům, hemoglobinu, Bence-Jonesovu proteinu a mukoproteinům.

**Falešná pozitivita:** u vzorků močí s vysokou spec. hmotností a dále u vzorků močí s alkalickým pH nad 8. V tomto případě použijte chemickou zkoušku (kys. sulfosalicylová) viz. výše. Dále také kontaminace moči NH<sub>4</sub><sup>+</sup> ionty (dezinfekční činidla a detergenty) mohou rovněž vyvolat pozitivní výsledky.

**Urobilinogen:** Reakční zóna obsahuje stabilní aromatickou diazoniovou sůl v kyselém pufru (p-diethylaminobenzaldehyd), která dává s urobilinogenem a sterobilinogenem růžové až karmínově červené zbarvení.

Výrazně zbarvené sloučeniny, jako např. azobarviva nebo riboflavin, mohou maskovat barevnou reakci.

**VIII. Dusitany:** Nitráty obsažené v moči se mohou působením některých patogenních bakterií redukovat na nitrity. Důkaz nitritů je pak nepřímým důkazem patologické bakteriurie, a tedy i infekce moč. ústrojí. Nitrity reagují se sulfonamidem v kyselém nárazníku (kys. p-arsanilová) za vzniku diazoniové soli, která kopuluje s chinolinovým chromogenem za vzniku růžového zbarvení. Test je specifický pro *Escherichia coli*, *Klebsiella*, *Aerobacter*, *Salmonella*, dále některé kmeny enterokoků, stafylokoků a *pseudomonas*. Reakce na nitrity je specifická, není ovlivněna bakteriální kontaminací čerstvě vymočené moči. Pozitivita je podmíněna nejen přítomností redukujících bakterií, ale i dostatečnou koncentrací nitrátů v moči a dostatečnou dobou působení bakterií v moč. měchýři.

Citlivost reakce snižuje vysoká spec. hmotnost vzorku, vysoké dávky vit. C.

**Falešná pozitivita:** Podávání léků na bázi fenazopyridinu

**Leukocyty (test esterázové aktivity granulocytů):** Esteráza granulocytů štěpí substrát na indoxyl, který dále reaguje s diazoniovou solí.

Rostoucí koncentrace glu (160mmol/l) nebo vysoká spec. hmotnost může snížit výsledky stanovení. Každá látka, která abnormálně zbarvuje moč, může maskovat průběh reakce např. nitrofurantoin.

## Urinalysis Reagent Strips Users Guide

### General Summary

This guide instructs the methods, reaction principles and points for attention for the use of Dirui Reagent Strips.

Dirui Reagent Strips are made for urinalysis of both qualitative and semi-quantitative, which are in vitro reagent for diagnostics. The strips are for professional use only. Reagent Strips are the primary testing product for the diseases of abnormal kidney diabetes, damage of kidney, serious infection and abnormal liver function. Assay of microalbumin has the significance for inspection of kidney transplant and the ability to differentiate the diseases caused from renal tubular and glomerulus's of the kidney. The excretion level of microalbumin has a direct impact on the variety degree of permeability of glomerulus's. In clinic field, the content of microalbumin in urine is detected as the significant parameter for damage of glomeruli.

The results on the strips can be read visually and instrumentally. You are required to read the User's Guide before taking use of the strips. The following chart tells the type of strips and the items tested.

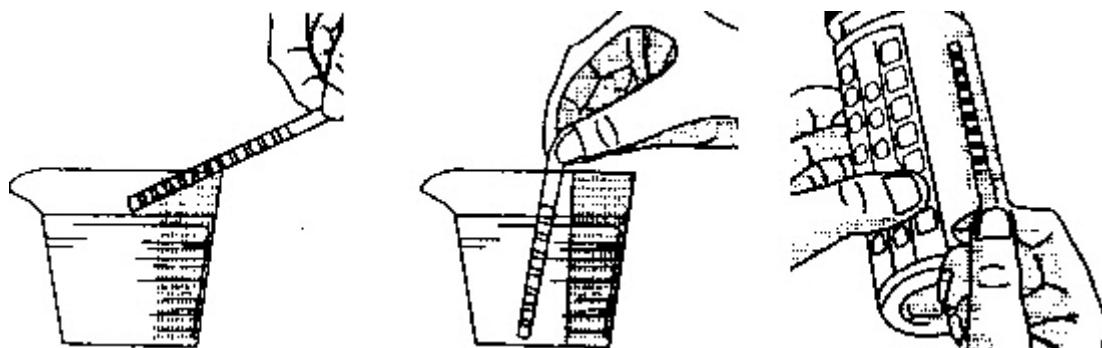

### Collecting and Preparing A Specimen

Collect a fresh urine sample in a clean and dry container. Don't centrifuge the urine. Mix the sample well before taking the test. The urine test must be taken within an hour. All specimens must always be taken and kept under sanitary conditions.

Note: Water should not be used as negative control liquid. The preservatives will not prevent the deterioration of Ketones, bilirubin or urobilinogen. The growth of bacteria in the long-term storage specimen may affect the test results on glucose, pH, nitrite and blood.

### Visual Reading Technique

1. Promptly replace cap after taking out strip
2. Immerse the reagent area of the strip in the urine specimen and take it up quickly and immediately
3. Run the edge of the strip against the rim of the container to remove the excess urine
4. Hold the strip up horizontally and compare the result on the strip with the colour chart on the bottle label closely. Make note of the result. For a semi-quantitative result, take the result according to the time specified on the colour chart. The pH and Protein can be read at any time within 60 seconds after dipping. For a qualitative result, the strip should be read between 1-2 minutes after dipping. If a positive result is obtained, repeat the test and compare with the colour chart at the time specified. Colour changes beyond 2 minutes are of no diagnostic value.

## Instrumental Reading Technique

Follow the directions given in appropriate instrument-operating manual.

### Storage

The strips must be kept in the original bottle. Never use the products after the expiration date. Every strip can be used only once. Do not remove the desiccant(s). Don't take the strips from the bottle unless it is for immediate use. Cap the bottle immediately and tightly after taking out the strips. The strips should be stored in a dry place at a temperature between 2° c -30° c'. Don't store the strips in a refrigerator and keep them away from direct sunlight. Do not touch the reagent area of the strip. PROTECTION AGAINST AMBIENT MOISTURE, LIGHT AND HEAT IS ESSENTIAL TO GUARD AGAINST ALTERED REAGENT REACTIVITY. Deterioration may result in discoloration or darkening of the reagent area of the strip. If all these happen, or the test results are questionable or inconsistent with the expected results, check and make sure the strips are within the expiration date and also compare with a control urine sample. Please dispose the used strips as waste according to Treatment Regulations of Lab Biohazard Materials.

### Limitation of Procedures

Like all the other laboratory tests, definitive diagnostic or therapeutic decisions should not be made or based on any single result or method.

### Reaction Principles

**Glucose:** The glucose oxidized by glucose oxidase catalyzes the formation of glucuronic acid and peroxide hydrogen. Peroxide hydrogen releases neo-ecotypes oxide (O) under the function of peroxidase. (O) oxidizes Iodide potassium, which makes the colour change.

**Bilirubin:** The direct bilirubin and dichlorobenzene diazonium produce azo dyes in a strongly acid medium.

**Ketone:** The acetoacetic acid and sodium nitroprusside cause reaction in the alkaline medium, which produces a violet colour.

**Specific Gravity:** Electrolyte (M X) in the form of salt in urine reacts with poly methyl vinyl ether and malefic acid (-COOH), which are weak acid ionic exchangers. The reaction produces hydrogenous ionogen, which reacts with pH indicator that causes the colour change.

**Blood:** Haemoglobin acts as peroxidase. It can cause peroxide release neo-ecotypes oxide (O) oxidizes the indicator and makes the colour change subsequently.

**pH:** The method of the pH indicator is applied.

**Protein:** This is based on the protein-error-of-indicator principle. Anion in the specific pH indicator attracted by caution on the protein molecule makes the indicator further ionized, which changes its colour.

**Urobilinogen:** Urobilinogen and diazonium produce pink azo dyes under the function of a strong acid medium.

**Nitrite:** Nitrite in the urine and aromatic amino sulphamamide are diazotized to form a diazonium compound. The diazonium compound reacting with tetrahydro benzo (h) quinolin 3-phenol causes the colour change.

**Leukocytes:** Granulocyte leukocytes in urine contain esterase's that catalyze the hydrolysis of the pyrrole amino acid ester to liberate 3-hydroxy 5-phenyl pyrrole. This pyrrole reacting with diazonium forms a purple colour.

\***Microalbumin:**\* (A11 only) Sulfone phthalein dye has a high sensitivity to microalbumin by the method of protein error.

## Points for Attention

### \*Protein and microalbumin\* (A11 Only)

Protein and microalbumin are more sensitive to albumin than Bence-Jones proteins, immunoglobulin and haemoglobin. When it is negative, it doesn't mean that protein does not exist.

## Glucose

The test is specific for glucose. No substance in urine other than glucose is known to show a positive result. 2.2mmol/L glucose in dilute urine containing 0.28mmol/L ascorbic acid may produce a colour change that might be interpreted as positive. Ascorbic acid concentrations of 0.28mmol/L and/or acetoacetic acid concentrations (1.1mmol/L) or lower may not influence the test. Normally, a small amount of glucose may be excreted through the kidney. The amount is usually below the sensitivity of the reagent test.

## Bilirubin

Normally, even the most sensitive method can't detect bilirubin in urine. It is abnormal to have little bilirubin in urine, which requires further inspection. Medicines that dye urine red and anything that shows red itself in an acid medium, e.g. phenazopyridine may affect the test result. High concentration of the ascorbic acid may cause a false negative result.

## Ketone

The reagent strip reacts with acetoacetic acid in urine. It doesn't do with acetone or  $\beta$ -hydro butyric acid. Normal urine specimens usually conduct negative results in the test. False positive results may occur in highly pigmented urine or those containing a large amount of levodopa metabolites.

## Specific Gravity

The reagent strip for Specific Gravity allows the urine specimens specific gravity between 1.000 and 1.030. In general, the mean error between the results of the strip test and those from the refractive index method is only 0.005. To make it more accurate, 0.005 may be added to readings from urine's with pH equal or greater than 6.5. Urine reading instruments can automatically make these adjustments in strip-readings. The urine non-ionic constituents such as glucose or radiopaque dye won't make any changes in the test. Highly buffered alkaline urine's may cause the low readings compared with the other methods. Elevated specific gravity readings may occur in the presence of moderate quantities of protein (1.75g/L).

## Blood

'Trace' reaction may vary among the patients. Clinical judgments are required for individual cases. The presence of green spots (intact erythrocytes) or green colour (haemoglobin/myoglobin) on the reagent area within 60 seconds indicates for further diagnostic checks. Blood is often found in the urine of the menstruating females. Haemoglobin 150-620  $\mu$  g/L is approximately equivalent to 5-15 cells/ $\mu$  L intact erythrocytes. The reagent strip is highly sensitive to haemoglobin and thus can be used as a supplementary to the microscopic examination. The sensitivity of the strip might be reduced in urine with a large amount of specific gravity. The strips are equally sensitive to myoglobin as to haemoglobin. Certain oxidizing contaminants, such as hypochlorite may lead to false positive results. Microbial peroxidase associated with urinary tract infection may also produce a false positive result. Ascorbic acid less than 5.Ommol/L in urine may not influence the result of the test.

## pH

The pH test area measures pH values in the range of 5.0-9.0 instrumentally and 5.0-8.5 visually.

## Urobilinogen

The reagent strips can detect urobilinogen in low amount as 3 µ mol/L (approximately 0.2 Ehrlich unit/dL) in urine. A result of 33 µ mol/L in urine indicates the critical value, representing the transition from normal to abnormal, which requires further check on patients and specimens. The negative results are not final to determine the absence of urobilinogen.

## Nitrite

Gram-negative bacteria in urine converts nitrate (derived from foods) into nitrite. The reagent strip is essential to nitrite and won't react with other substances in urine. Pink spots or edges on the strip should not be interpreted as positive result. But any degrees of uniform pink colour development should be taken as positive result. The degrees of colour development and the numbers of bacteria are not in direct proportion. The negative result doesn't mean the existence of bacteria in a large amount.

Negative results may occur:

1. When urine doesn't contain the organism that caused the conversion from Nitrate to Nitrite.
2. When urine has not remained in the bladder long enough (four hours +) to let the nitrate convert to nitrite.
3. The nitrate in the foods is absent. Large high volume of specific gravity in urine may reduce the sensitivity of the test. 2.8mmol/L ascorbic acid or less won't interfere with the test result.

## Leukocytes

Test areas react with esterase in leucocytes (granulocytic leukocytes). Normal urine specimens generally yield negative results; positive results (+ or greater) are clinically significant. Individually observed 'Trace' results may be of questionable clinical significance; however 'Trace' results observed repeatedly may be clinically significant. 'Positive' results may occasionally be found with random specimens from females due to contamination of the specimen by vaginal discharge. Elevated glucose concentrations (160mmol/L) or high specific gravity may cause decreased test results.

## Protein: (Not A11 See \*Protein and microalbumin\* (A11 Only))

The reagent area is more sensitive to albumin than to globulins, haemoglobin, Bence Jones protein and mucoprotein. So a 'Negative Result' is not good enough to indicate that these proteins don't exist in urine. Normally no protein is detectable in urine with conventional methods, although a minute amount of protein is excreted through a normal kidney. It shows the protein in urine when the colour is darker than the mark on the chart. False positive results may be obtained in highly buffered alkaline urines. Urine specimens contaminated with quaternary ammonium compounds and cleansers containing chlorhexidine may also produce false positive results.

**SENSITIVITY AND TEST RANGE OF URISTIK URINALYSIS STRIPS****SPECIFIC PERFORMANCE CHARACTERISTICS**

Specific performance characteristics are based on clinical and analytical studies. In clinical specimens, the sensitivity depends upon several factors; the variability of colour perception, the presence or absence of inhibitory factors typically found in urine, specific gravity, pH, and the lighting conditions when the product is read visually. Each colour block or instrumental display value represents a range of values. Because of specimen and reading variability, specimens with analyte concentrations that fall between nominal levels may give results at either level. Results at levels greater than the second positive level for the Protein, Glucose, Ketone, and Urobilinogen tests will usually be within one level of the true concentration. Exact agreement between visual results and instrumental results might not be found because of the inherent differences between the perception of the human eye and the optical system of the instruments.

**Reactive ingredients (based on dry weight at time of impregnation)**

Protein: 0.1% w/w tetrabromphenol blue; 97.4% w/w buffer: 2.5% w/w non reactive ingredients.

Blood: 26.0% w/w diisopropylbenzene dihydro peroxide; 1.5% w/w tetramethylbenzidine; 35.3% w/w buffer; 37.2 % w/w non reactive ingredients.

Glucose: 1.7% w/w glucose oxidase (microbial 123U); 0.2% w/w peroxidase (horseradish. 203 IU); 0.1 % w/w potassium iodide; 71.8% w/w buffer; 26.2% w/w non reactive ingredients.

Ketone: 5.7% w/w sodium nitroprusside; 29.9% w/w non reactive ingredients: 64.4% w/w buffer.

Leukocytes: 4.3% w/w pyrrole amino acid: 0.4% w/w diazonium salt; 92.6% w/w buffer, 2.7% w/w non reactive ingredients.

Nitrite: 1.3% w/w p-arsanilic acid; 0.9% w/w tetrahydroquinoline N-(1-Naphthol)-ethylenediamine; 89.6%, w/w buffer; 8.2% w/w non reactive ingredients.

Specific Gravity: 4.8% w/w bromthymol blue; 90.2% w/w poly(methyl vinyl ether co maleic anhydride); 5.0% w/w sodium hydroxide.

pH: 3.3% w/w bromcresol green; 55.0% w/w bromthymol blue: 41.7% w/w non reactive ingredients.

Bilirubin: 0.6% w/w 2.4 -dichlorobenzene amine diazonium salt; 57.3% w/w buffer; 42.1% w/w non reactive ingredients.

Urobilinogen: 0.2% w/w fast blue B salt; 98.0% w/w buffer; 1.8% w/w non reactive ingredients.

\*Microalbumin:\* (A11 Only) 2.2% w/w sulfone phthalein; 98.0% w/w buffer; 1.8% w/w non reactive ingredients.

**\*The Common Question For Microalbumin Testing\* (A11 Only)**

1. The reason for the testing of microalbumin.

The assay of microalbumin has the early detection for several diseases.

a) Practical value for the patient of high blood pressure: the excretion rate of microalbumin for high blood pressure patients is obviously higher than one for a normal person. The increasing microalbumin is the important forecast parameter for cardiovascular disease.

b) Microalbumin can forecast the development of diabetic nephropathy and early detection. Because the earliest clinical signal for diabetic nephropathy is the presence of microalbumin in urine. It is very helpful for diabetes: patients to take earlier measures to protect the function of the kidney.

c) The assay of microalbumin is the sensitive indicator for diabetic complication of micro vessel.

2. Clinical significance of positive result of microalbumin

a) If the strip has the positive result on microalbumin, it is necessary to test urine the sample consecutively for several days. If microalbumin is casually present, it could be physical proteinuria. for example, it might be caused from diet, exercise or stress.

b) If the positive result is consecutively present, or the positive result on blood and microalbumin simultaneously or positive result on glucose and microalbumin simultaneously, it is suggested that the result of microalbumin should be confirmed by the method of immuno turbidimetry.
